ABSTRACT

The issue of SVMs parameter optimization with particle swarm optimization (ps) provide the optimum solution. This new classification approach may be an efficient alternative, in existing paradigms. PSO technique work with high dimensional datasets and mixed attribute data. The structure of the image is recognized through PSO technique which provide optimized parameter for SVM. This approach determines the performance of image classification after structural recognition based on content of image and comparing the obtained results with those reported for various other classification approaches. PSO-SVM technique can be applied mixed-attribute, hyperspectral data, hyperdimension spaces & problem description spaces and it can also be a competitive alternative to well established classification techniques. The optimized process of data reduces the unclassified region of support vector machine and improves the performance of image classification. The feature of region of image is classified by PSO-SVM technique in inside the image. Classified features are increase recognition ratio because the feature of image is optimized.

General Terms

Pattern Recognition, high dimensional image classification et. al.

Keywords

Structural recognition, PSO technique, SVM classifier, image classification.

1. INTRODUCTION

Nowadays, Technology in digital image processing is emerging rapidly. So, the accuracy and performance of images in the field of image recognition, image segmentation, image reconstruction & image classification plays a vital role in digital image processing. My research work in Content based image recognition then classification of images are a key part of digital image processing. The enlargement in the computer technologies and the advent of the Nation wise Wide Web, there has been an explosion in the amount and complexity of digital data being generated, stored, transmitted, analyzed, and accessed. In order to make use of this vast amount of data, efficient and effective techniques to retrieve multimedia information based on its content need to be developed. Image recognition is challenging & new emerging field of image processing. This application importance in image analysis and design field. The image content is color, texture and shape[11].

The major image feature is the structure of the object contained in the image Shape feature of the image may be defined as the characteristic surface configuration of an object; an outline or contour[18]. Shape representations can be generally divided into two categories:

- Boundary-based, and
- Region-based.

The shape of an object is a binary image representing the extent of objects. In region-based considers the shape being composed of a set of two-dimensional regions, while the boundary based representation presents the shape of its outline. Region-based feature vectors often result in shorter feature vectors and simpler matching algorithms. Object region features are recognized on the basis of pixel values in digital image processing.

Recently evolutionary algorithms are used for optimization & Recognition:

1. Genetic algorithm (GA).
2. Particle swarm optimization (PSO)
3. Ant colony optimization (ACO)
4. Simulated annealing algorithm (SA)

This Algorithm has been employed to optimize the SVMs parameters for their better global search abilities against numerical optimization methods[23]. PSO algorithm is responsible for optimum solution for parameters selection. Particle Swarm Optimization (PSO) algorithm is a global optimization method originally [1] [2]. It is swarm intelligence algorithm that emulates swarm behaviors such as birds flocking and fish schooling[3]. It is a population-based iterative learning algorithm that shares some common characteristics with other evolutionary computation (EC) algorithms [25]. The PSO algorithm works with noisy images. This algorithm efficiently work with edge detection, line detection and point detection[24].

For the classification of lower content of the image we used support vector machine. Support vector machine is a linear and bilinear classifier [5]. Machine Learning is considered as a subfield of Artificial Intelligence and it is concerned with the development of techniques and methods which enable the computer to learn. Image recognition is a basic step of Machine learning.

Special attention is given to two major potential problems encountered in the classification domain: datasets with high dimensionality and mixed attribute with noisy data[20]. Particle Swarm Optimisation (PSO) is a population-based meta-heuristic method for solving global and local optimisation problems based on social-psychological principles[22]. Compared with some heuristic methods such as genetic algorithms, the most important general advantages of PSO are ease of its implementation, memory for each particle and high speed of convergence[25].

2. RELATED WORK

Particle Swarm Optimization (PSO) algorithm is a global optimization method originally. It is swarm intelligence algorithm that emulates swarm behaviors such as birds flocking and fish schooling. It is a population-based iterative learning algorithm that shares some common characteristics with other evolutionary computation (EC) algorithms. ACO makes probabilistic decision in terms of the artificial pheromone trails and the local heuristic information. This allows ACO to explore

larger number of solutions than greedy heuristics. Another characteristic of the ACO algorithm is the pheromone trail evaporation, which is a process that leads to decreasing the pheromone trail intensity over time. It is suggested by Qin Da et al[13].

Addressing the issue of SVMs parameters optimization, this study proposes an efficient memetic algorithm based on particle swarm optimization algorithm (PSO) and pattern search (PS). In the proposed memetic algorithm, PSO is responsible for exploration of the search space and the detection of the potential regions with optimum solutions, while pattern search (PS) is used to produce an effective exploitation on the potential regions obtained by PSO. This is worked by Yukun Bao et al[22]. Support vector machine (SVM) is the state-of-the-art classification method, and the doubly regularized SVM (DrSVM) is an important extension based on the elastic net penalty. DrSVM has been successfully applied in handling variable selection while retaining (or discarding) correlated variables. However, it is challenging to solve this model. This is suggested by Dehua Liu[25]. This study initially aims at optimizing the accuracy of SVM classifier by detecting the subset of best informative features and estimating the best values for regularization of kernel parameters for SVM model[16]. In order to achieve this PSO based optimized framework is used. PSO-SVM algorithm combines two machine learning methods by optimizing the parameters of SVM using PSO with fast feature extraction method. PSO starts with n-randomly selected particles and searches for the optimal particle iteratively. Each particle is a m-dimensional vector and represents a candidate solution. SVM classifier is built for each candidate solution to evaluate its performance through the cross validation method. PSO algorithm guides the selection of potential subsets that lead to best prediction accuracy[16]. The algorithm uses the fit particles to contribute to the next generation of n-candidate particles. Thus, on the average, each successive population of candidate particles fits better than its predecessor. This work is Fatima Ardjani et al[16].

2.1 PSO Technique

PSO was first described by James Kennedy and Russell Eberhart in 1995. This algorithm apply in noisy feature of images. This algorithm is swarm intelligence based. The observatzion of swarming habits of animals such as birds or fish. The PSO algorithm maintains multiple potential solutions at one time. During each iteration of the algorithm, each solution is evaluated by an objective function . Each solution is represented by a particle in the fitness landscape (search space).The particles “fly” or “swarm” through the search space to find the maximum value returned by objective function.

The PSO algorithm consists of just three steps:

1. Evaluate the fitness of each particle.
2. Update individual and global best.
3. Update velocity and position of each particle.

These steps are repeated until some stopping condition is met. Performance of particle is fitness of each particle. (local best value is the fitness value of particle). Each particle’s velocity is updated using this equation:

$$v_i(t+1) = wv_i(t) + c_1r_1[\hat{x}_i(t) - x_i(t)] + c_2r_2[g(t) - x_i(t)] \dots \dots \dots (1)$$

where,

i is the particle index.

w is the inertial coefficient.

c1, *c2* are acceleration coefficients.

r1, *r2* are random values .

Regenerated every velocity update particle.

v_i(t) is the particle’s velocity at time *t*.

x_i(t) is the particle’s position at time *t*.

xi[^](t) is the particle’s individual best solution as of time *t*.

g(t) is the swarm’s best solution as of time *t*.

Each particle’s position is updated using this equation:

$$x_i(t + 1) = x_i(t) + v_i(t + 1) \dots \dots \dots (2)$$

Particle Swarm Optimization (PSO) algorithm is a global optimization method originally [1][2]. It is swarm intelligence algorithm that emulates swarm behaviors such as birds flocking and fish schooling[8]. It is a population-based iterative learning algorithm that shares some common characteristics with other evolutionary computation (EC) algorithms [3]. However, particle flying in the search space and adjusting its flying trajectory according to its personal best experience and its neighborhood’s best experience rather than through particles undergoing genetic operations like selection, crossover, and mutation [4]. Owing to its simple concept and high efficiency, PSO has become a widely adopted optimization technique and has been successfully applied to many real-world problems [8]. PSO searches for an optimum through each Particle swarm optimization (PSO) relies on its learning strategy to guide its search direction. Traditionally, each particle utilizes its historical best experience and its neighborhood’s best experience through linear summation. Such a learning strategy is easy to use.

2.2 Support Vector Machine

Support vector machine is a linear and bilinear classifier[18]. Support Vector Machine (SVM) was first heard in 1992, introduced by Bose, Guyon, and Vapnik in COLT-92. Support vector machines (SVMs) are a set of related supervised learning methods used for classification and regression [8]. They belong to a family of generalized linear classifiers. In other terms, Support Vector Machine (SVM) is a classification and regression prediction tool that uses machine learning theory to maximize predictive accuracy while automatically avoiding over-fit to the data. Support Vector machines can be defined as systems which use the hypothesis space of a linear function in a high dimensional feature space, trained with a learning algorithm from optimization theory that implements a learning bias derived from statistical learning theory[25]. It is also being used for many applications, such as handwriting analysis, phase analysis and so forth, especially for pattern classification and regression based applications. The foundations of Support Vector Machines (SVM) have been developed by Vapnik and gained popularity due to many promising features such as better empirical performance.

SVM is a novel neural network technique, which can be applied in classification and regression analysis. Consider a training data set $\{(x_i, y_i)\}_{i=1}^n$ where x_i presents the input vector and $y_i \in \{1, -1\}$ presents the class label. Determination of optimum hyper plane can be used to solve the following optimization problem:

$$\text{Min} \quad \frac{1}{2} \|w\|^2 \dots \dots \dots (3)$$

Subject to

$$y_i(w \cdot x_i + b) \geq 1$$

In order to solve the above optimization problem, two positive slack variables are introduced. Then, the optimization problem is given as follows:

$$\text{Min} \quad \frac{1}{2} \|w\|^2 + C \sum_{i=1}^n \xi_i \dots \dots \dots (4)$$

$$y_i(w \cdot x_i + b) \geq 1 - \xi_i, \quad \xi_i \geq 0$$

where ξ_i, ξ_i' are the slack variables; *C* is a regularization constant. Finally, the classification function is written as follows:

Figure 2: Satellite image1

Here figure 1 shows that the main satellite image, which is read first, and in the next step the input query image is proceed for the selected region of interest with accordingly similar classified image.

Figure 3: Region of Interest

Now here figure2 shows that the selected region of interest of the input taken image before. And figure 3 shows that the highlighted region of the image taken for testing.

Figure 4: Region based classified image

Here table 1 shows that the accuracy, kappa coefficient value of the satellite and Land Sat image on the basis of confusion Matrix. The analysis is done on the basis of existing work. The existing technique is being trained using SVM training and hence the accuracy is less. In the table shows the accuracies of different image taken for the testing. Kappa value represent the categorical value of features. Kappa coefficient (k), which is believed to be a better representation of the general quality of an image classification, because it removes the effects caused by differences in sample size and accounts for the off-diagonal elements in the error matrix. It also allows different classifications to be compared statistically.

Table 1: Accuracy comparison of SVM and PSOSVM

kappa value	With SVM	With PSOSVM
0.4525	81.6551	89.5652
0.4752	82.5475	87.5641
0.3954	81.6594	85.6621
0.4215	82.5475	88.2245
0.4712	82.7594	91.6583
0.3953	86.6547	90.5264
0.5445	84.3162	89.4545

As shown in the figure 4 is the result analysis and comparison of the SVM method and PSOSVM proposed method. The analysis shows the performance of the proposed PSOSVM, the proposed technique has more accuracy as compared to the only SVM method.

Figure 5: Comparison of SVM technique with Proposed PSOSVM method

Recognition rate of image is much more to other techniques with PSOSVM because classification accuracy is enhanced.

Results are described with other techniques-

Figure 6: The classification accuracy of PSO-SVM compared with SVM, BP neural network, RBF neural network.

- Due to randomized aspects of PSO algorithm, the optimization process would need to be run several times to determine if results are consistent.
- Alternative PSO parameters can be attempted, and their effectiveness measured.

5. CONCLUSION

Significant speedup using PSO over exhaustive search. This technique provides the optimum solution efficiently for the image classification after image recognition as compare to other techniques. Another alternative can be used as pso technique. In my research study, recognition of images with pso techniques for classification using svm provide better result as compared to other techniques (such as ACO optimization, neural network and radial basis network). PSO algorithm with SVM working with efficiently and recognition performance is is increased compare

to other techniques. PSO Algorithm’s modification or alternative will be apply in the future.

6. FUTURE WORK

The Limitation of the PSO approach when the number of classes is important in multiclass databases. From the reported classification performances for various datasets, the results clearly indicate that PSO out performed other classification methods in accuracy. Nevertheless, the time consumption of the training stage is substantially higher than with other techniques. The other alternative can be used in which time consumption problem would be removed.

8. AUTHERS' PROFILE

Abhishek Pandey (Birth Place-Rewa(M.P.) D.O.B.-01.05.1987) received his Bachelor’s degree in Information technology from SATI Vidisha,(m.p.) India in 2010.

At present, he is pursuing M.E. degree in Computer Science & Engineering from UIT- RGPV, Bhopal India. His research areas are Image processing, recognition & classification.

Prof. Anjna jayant deen (Birth Place- Bhopal, D.O.B.-22.07.1973) has received her Bachelor’s degree in Computer Science & Engineering from UIT (GEC)-RGPV, Bhopal India in 1993, and completed M.Tech., degree from Maulana Azad National Institute of Technology, Bhopal, India in 2007.

At present, She is working as an Assistant Prof. in UIT-RGPV Bhopal since 2007. She has been published in various research papers in National and International Journal. Her areas of interest include Computer Networks, Neural Networks and Internet.

Dr. Rajeev Pandey received his Bachelor’s degree in Computer Science & Engineering from IET, DR. B.R.A. University Agra, U.P. India.M.E. (Computer Science & Engineering) from Dr. B.R.A. University, Agra in 2004. Ph.D. in 2010 from Dr.B.R.A. University, Agra, U.P. India. He is also Pursuing Ph.D. (Computer Science & Engineering) from RGPV, Bhopal, M.P. India. At present, he is working as an Assistant Prof. in UIT-RGPV, Bhopal since 2007.
